

# Reflection Prompts for Math 17 — Spring 2023

Taylor Dupuy

January 17, 2023

This document contains all of the reflection questions for Math 17. There are no right or wrong answers to these questions and really count as a participation grade. When asked to do one of these reflection questions, find the question, think about the idea, and then write a response on a separate sheet of paper. Please include the date, your name, and the title of the reflection on your work.

## 0.1 Calculators

We often take calculators for granted. Find your nearest calculator and input  $31 + 10^{-16}$ , that is, try to get it to perform the addition  $31 + 0.0000000000000001$  (you can use your smart phone or Google). What happens? Why do you think this happens?

## 0.2 What is Ranked Choice Voting?

In 2009 Burlington had an election for Mayor in which there were three candidates. At the time the city implemented "ranked choice voting" which is a system in which voters submit a ballot which ranks their preferred order of candidates. How do you suppose this worked? Make up some rules that would allow you to elect a mayor to take into account the voters will using these ranked ballots. How would you determine the winner if you were allowed to make up a voting system? Why?

## 0.3 Flipping Coins

Produce a sheet of paper with 100 coin flips recording a sequential number of heads and tails. There are two ways you can do this. You can cheat and just write down a bunch of heads and tails or you actually flip a coin 100 times. All I ask is that you don't mix these two ways of completing this assignment. Either completely cheat and just write down random heads and tails or you actually flip coins and do this for the entire 100 flips. When you submit the assignment don't say which method you used.

## 0.4 Expected Values Are Everywhere

Expected values are everywhere. They can be used in games, psychology experiments, interpersonal relationships, business, biology, and elsewhere. Find a probabilistic system whose expected value you are interested in.

## 0.5 The Monty Hall Problem

You are the contestant on *Let's Make A Deal* with host Monty Hall. In this game there are three doors. Behind two of the doors there are goats and behind one of the doors is a brand new car. Your job is to guess which door has the car and if you get it right, you get the car. Monty asks you to select a door. After your selection he reveals goats behind one of the doors. You are allowed to stay with your current door or switch. What should you do? Should you stay with your current door? Should you switch to the new door? Does it matter?

## 0.6 Bernoulli's Game

<sup>1</sup> Consider the following five dollar carnival game. In this game, you are asked to repeatedly toss a coin and the game stops the first time you flip heads. The payout structure is as follows:

- if you flip heads (H) your first try you get \$1.
- if you flip tails then heads (TH) you get \$2.
- if you flip two tails then a heads (TTH) you get \$4.
- if you flip TTTH you get \$8.
- ...

The pattern keeps going with the payout doubling for each tail you flip in a row. Should you play this game? How much should you pay to play this game?

## 0.7 Seven Bridges of Koenigsburg

Euler lived in the city of Koenigsburg (modern day Kaliningran adjacent to Finland). The city had a system of bridges as mapped out below. Euler wanted to walk across each one of the bridges exactly once in the city. Try this problem and write out your thoughts on the problem.

## 0.8 3 Houses and 3 Utilities

My 5th grade teacher math Mrs. Kelly gave me the following problem in 1995: There are three houses and three utilities as pictured below.
